

PURBANCHAL UNIVERSITY

Final Year Project Report on

Online Shopping System

[AcmeShop.com]

In the partial fulfillment of the requirement for the award of the degree of
Bachelor in Computer Engineering

Submitted By:

Bikash Shrestha [381535]

Dimpal Ruchal [381537]

Kushum Tamang [381538]

Sudip Rijal [381553]

Under the Support and Guidance of

Er. Ananta Adhikari

Acme Engineering College

Sitapaila, Kathmandu, Nepal

Department of Computer, Electronics and Communication Engineering

August, 2023

BONAFIDE CERTIFICATE

The is to certified that this project “Online Shopping System” is the bonafide work of Bikash Shrestha, Dimpal Ruchal, Kushum Tamang and Sudip Rijal who carried out the project under my supervision.

APPROVAL CERTIFICATE

We have pleasure in forwarding the project work of Bikash Shrestha, Dimpal Ruchal, Kushum Tamang and Sudip Rijal entitled “Online Shopping System” for the award of the degree of Bachelor in Computer Engineering.

They have successfully completed the project work for prescribed period and the project embodied the result of their investigation conducted during the period they worked as full-time student of this college.

ACKNOWLEDGEMENTS

We would like to extend our heartfelt gratitude to our project coordinator **Er. Sarad Poudel**, our head of department, and our project supervisor **Er. Ananta Adhikari**. Their invaluable guidance and unwavering support were instrumental in the successful completion of our project on the 'Online Shopping System.' Their encouragement fueled our research efforts, enriching our knowledge and understanding of various aspects.

We would also like to express our deep appreciation to our parents and friends for their unending support and assistance. Their encouragement and understanding were indispensable in helping us complete this project within the allocated time frame.

Lastly, we extend our gratitude to 'Purbanchal University' for providing us with this golden opportunity to embark on this wonderful project. Their support has been pivotal to our academic journey, and we are truly thankful for it.

Project Group Member

Bikash Shrestha [381535]

ABSTRACT

Online shopping system is a digital platform that allows customers to browse, select, and purchase products or services through the internet. This project deals with developing an e-commerce website for online different types of products. Online stores are usually available 24 hours a day and many consumers have internet access both at work and at home. So it is very convenient for them to shop Online. It provides a user-friendly interface that simplifies the shopping experience, enabling customers to search for products, compare prices, and make informed decisions. It provides the user with a catalog of different types of products available for purchase in the store. The Online shopping system project has been developed to allow business grows larger and faster. This site will let consumer to view and order products online from any part of the world. Under this website many products and services can be ordered.

The Online shopping Web is designed from a user point of view. The user friendly design helps the users in accomplishing their task with ease. Attempts have been made to keep the design simple and understandable. The inception and evolution of this Online Shopping Web project adhere to an iterative Software Development Life Cycle (SDLC) model, fostering adaptability, creativity, and responsiveness. The iterative approach encourages continuous refinement and enhancement, leveraging user feedback to shape features and functionalities that align closely with user expectations and trends. The underlying programming languages, meticulously selected for their compatibility and efficiency, contribute to the project's robustness and performance. This project is built with modern technologies like PHP, JavaScript, MySQL etc. These technologies work together to make the website interactive, responsive, and able to store all the information about products and customers securely.

Chapter 1: Introduction

An online shopping system is like a digital shopping journey where people can buy things directly from sellers through the internet. It's like shopping in a virtual store from the comfort of your own space. This way of shopping uses the internet and is called electronic commerce or e-commerce. Imagine browsing a store's website and picking things you want to buy, just like you would in a physical store.

The concept of online shopping is built upon e-commerce platforms, which serve as virtual marketplaces where vendors and buyers converge. These platforms showcase an extensive range of products, from clothing and electronics to groceries and specialized services, catering to diverse consumer needs. With the proliferation of online retailers and marketplaces, shoppers can explore products from local and global sources, often finding unique and niche items that might not be readily available in their immediate vicinity.

The process of online shopping is characterized by simplicity and ease. Shoppers can use web browsers or dedicated mobile apps to peruse products, read detailed descriptions, view images, and even access customer reviews. This information empowers consumers to make informed decisions before adding items to their virtual shopping carts. Secure online payment gateways facilitate seamless transactions, and various shipping options allow products to be delivered directly to the shopper's doorstep.

Moreover, online shopping often offers cost-saving opportunities through digital coupons, discounts, and comparison tools that enable shoppers to find the best deals. This convenience and potential for savings have contributed to the growing popularity of online shopping across all age groups and demographics.

However, as with any technological advancement, online shopping also comes with considerations such as security, privacy, and the risk of fraudulent activities. It's important for both shoppers and online retailers to prioritize cybersecurity measures to safeguard personal and financial information.

In conclusion, online shopping has transformed the retail landscape by providing a virtual marketplace accessible to anyone with an internet connection. Its convenience, extensive product range, and potential for cost savings have made it an integral part of modern consumer culture, shaping the way we discover and acquire goods and services.

1.1 Background

Online shopping systems, also known as e-commerce platforms, are websites or applications that enable customers to purchase products or services over the internet. These systems have become increasingly popular over the past few decades, as more and more people have gained access to the internet and become comfortable with using technology to make purchases.

The history of online shopping systems can be traced back to the early days of the internet in the 1990s, when businesses began experimenting with selling products online. However, it wasn't until the late 1990s and early 2000s that online shopping began to really take off, as more people gained access to high-speed internet connections and as security protocols for online transactions improved. The late 1990s and early 2000s marked a turning point with the emergence of e-commerce giants like Amazon and eBay. These platforms not only offered an extensive array of products encompassing various categories but also introduced innovative features such as customer reviews, personalized recommendations, and user-friendly interfaces. These elements significantly enhanced the overall online shopping experience, setting new benchmarks for convenience and customer satisfaction.

The subsequent explosion of smartphones and the proliferation of mobile apps brought about another significant shift in online shopping behavior. With the ability to access e-commerce platforms anytime and anywhere, consumers were no longer confined to their desktop computers. The convenience of shopping on-the-go further propelled the growth of online shopping and ushered in an era where mobile optimization became a key consideration for online retailers.

Today, online shopping systems are supported by robust e-commerce platforms, which provide retailers with the tools they need to create and manage their online stores. These platforms offer a wide range of features, such as product catalogs, shopping carts, payment gateways, and order fulfillment systems.

Overall, the background of online shopping systems is rooted in the growth of the internet and advancement in technology. As e-commerce continues to grow and evolve, we can expect online shopping systems to become even more sophisticated and convenient for consumers. Online shopping systems also come with their own set of challenges, including issues around security, privacy, and customer service. As the market for e-commerce continues to evolve, these challenges will continue to be addressed and overcome in new and innovative ways. [1]

1.2 Project Objectives:

Project objectives serve as the guiding pillars that direct the course of a project from its initiation to its successful completion. These objectives define the purpose and scope of the project, outlining the specific outcomes and goals that need to be achieved. They act as a roadmap for the project team, stakeholders, and collaborators, ensuring that efforts are aligned and resources are utilized efficiently. Following are the objectives of our project:

1.2.1 Generic Objectives:

- To provide customers with a convenient, user-friendly, and secure way to purchase goods and services online, while also providing them with a wide selection of products.

1.2.2 Specific Objectives:

- To provide a product catalog that includes details such as product name, description, price and availability.
- To provide a shopping cart that allows customers to add products to their cart and make modifications such as adding or removing products
- Allowing customers to leave feedback.

1.3 Project Scope:

This system can be implemented to any shop in the locality or to multiple branded shops. The system recommends a facility to accept the orders 24*7 and a home delivery system which can make customers happy. It typically includes user registration and authentication for secure access, a comprehensive product catalog showcasing various items with detailed descriptions and pricing information. The system allows users to add products to a virtual shopping cart, modify quantities, and proceed to checkout through secure payment processing. Searching features enable users to find specific products based on their preferences, and also can provide valuable feedback. If shops provide this online portal their customers can enjoy easy shopping from anywhere. It is easily accessible and always available through internet.

Features of this system are:

- 24/7 Order Acceptance: The system operates round the clock, allowing customers to place orders at any time that suits them, providing flexibility and convenience.

- Home Delivery: The system includes a home delivery service, ensuring that customers receive their ordered items at their doorstep. This feature enhances customer satisfaction by eliminating the need for physical store visits.
- Comprehensive Product Catalog: The system showcases a wide range of products with detailed descriptions, high-quality images, and accurate pricing information. This helps customers make informed purchasing decisions.
- Virtual Shopping Cart: Users can add products to a virtual shopping cart as they browse the catalog. They can modify quantities, remove items, and review their selections before proceeding to checkout.
- Secure Payment Processing: The system ensures secure payment transactions.
- Search: The platform offers search features that allow users to quickly find specific products.
- Feedback: Customers can provide feedback on products they've purchased, which helps other users make informed choices and establishes a sense of trust in the system.
- Easy Accessibility: The online portal is easily accessible through the internet, enabling customers to shop from anywhere.

1.4 Problem Statement:

This project aims to develop an online shopping system for customers with the goal so that it is very easy to shop wanted products from extensive number of online shopping sites available on the web.

Despite the benefits of online shopping systems, there are still several challenges that businesses and consumers may face when using these systems. Here are some common problem statements of online shopping systems:

- Security concerns and technical issues: One of the biggest challenges with online shopping systems is security. Consumers may be hesitant to provide their personal and financial information online due to concerns about identity theft, fraud, and other malicious activities. Online shopping systems can be prone to technical issues such as website crashes, slow loading times, and payment processing errors, which can lead to frustrated customers and lost sales.
- Product Quality: Since customers are not able to see or touch products before they purchase them online, there may be concerns about product quality and accuracy. This

can lead to returns, refunds, and negative reviews, which can damage a business's reputation.

- Delivery Issues: Delays or errors in product delivery can result in lost sales and dissatisfied customers. Businesses must ensure that they have reliable shipping and delivery processes in place to avoid these issues.

Overall, the problem statements of online shopping systems center issues of security, technical difficulties, trust, product quality, and delivery and returns. Addressing these challenges can help businesses to provide a better shopping experience for customers and improve their bottom line.

Chapter 2: Literature review

2.1 Background:

Electronic Commerce (e-commerce) applications support the interaction between different parties participating in a commerce transaction via the network, as well as the management of the data involved in the process.

According to researchers conducted at (Graphics, Visualization, and Usability) Center at the Georgia Institute of Technology "e-commerce is taking off both in terms of the number of users shopping as well as the total amount people are spending via Internet based transactions"

The most cited reason for using the web for personal shopping was convenience (65%), followed by availability of vendor information (60%), no pressure from sales person (55%) and saving time (53%). Although the issue of security remains the primary reason why more people do not purchase items online, the GVA survey also indicates that faith in the security of ecommerce is increasing. [2]

A good e-commerce site should present the following factors to the customers for better usability:

- Knowing when an item was saved or not saved in the shopping cart.
- Returning to different parts of the site after adding an item to the shopping cart.
- Easy scanning and selecting items in a list.
- Effective categorical organization of products.
- Simple navigation from home page to information and order links for specific products.
- Obvious shopping links or buttons.
- Minimal and effective security notifications or messages.
- Consistent layout of product information.

2.2 Research based on similar projects:

For this project we researched few of other similar projects as reference for our project. One of them was titled 'online shopping' by 'Chaitanya Reddy Mittapelli'. This project was focused on making search engine in a shopping site more efficient. The project was an attempt to make very attractive and interactive online shopping site. Features were further expanded into account feature, subscription feature to subscribe product companies, refined shopping cart processes and advanced billing system. However this reference project seemed more complicated for our timeframe and resources we are provided. Another paper we studied was titled 'Online Shopping Cart' by 'Charu Sharma'. This project was fairly simple and lower scaled compare to previous project. This project had feature for accounts and it had ability to handle multiple users with simple interface. These two projects provided us a good sense of balance between quantity and quality of a project. This will be essential for proper time and resource management during later phases of the project. [3]

We looked at e commerce project by 'Bablu Agrahari' as reference for out project. Because of the well organize codes and documentation, the study of the project was easy. The project was especially good at empasizing on communication element between customer side and admin side. This gave us idea to give good accessibility feature to customers by the feature called "feedback". But it lacked in richness of facilities beyond that. Piyush Gupta's project was handled a lot of complication with wide range of products. It had well organized wide range of products without seeming like a just a cluster of product. The project however was not good in terms of features. [4]

Daraz:

We did research in Nepali online shopping site as e-commerce has rapidly expanded in Nepal, with platforms like Daraz playing a pivotal role. This literature review focuses on Daraz's features, user experience, challenges, and impact on the local e-commerce landscape in the context of an online shopping system project. As a prominent online marketplace under the Alibaba Group, Daraz offers a wide array of products and categories. Its user-friendly interface simplifies shopping, allowing customers to easily find and purchase items. The platform's strengths lie in its well-organized product catalog, multiple payment options, and efficient delivery network.

Despite its success, Daraz faces challenges like payment security, remote area delivery, and counterfeit products. However, the platform addresses these issues through secure payment gateways, improved logistics, and quality control measures. Daraz's adaptability is evident in

its innovative strategies to enhance user experience, including flash sales and promotional events. Daraz's entry significantly impacted Nepal's e-commerce landscape, influencing consumer behavior through its marketing campaigns and sales events. It has contributed to raising awareness about online shopping and played a role in shaping market dynamics by creating a trusted online marketplace.

Daraz's growth and impact underline its role in transforming Nepal's e-commerce scene. By offering a diverse range of products and services while addressing challenges, Daraz has established itself as a major player, contributing to increased online shopping awareness and shaping local consumer habits. [5]

Hamrobazar:

In Nepal's online shopping ecosystem, Hamrobazar stands out as a unique online classifieds marketplace. This literature review explores Hamrobazar's features, user experience, challenges, and its distinct influence on local e-commerce.

Hamrobazar differentiates itself by focusing on peer-to-peer transactions for used items. Its platform facilitates direct interaction between buyers and sellers, creating a straightforward avenue for users to exchange goods. The platform's simplicity and user-driven nature make it an accessible option for those looking to buy or sell second-hand items. One of Hamrobazar's challenges lies in verifying the authenticity of listings and ensuring user trust due to its decentralized nature. As an adaptation, the platform could potentially explore user reviews and enhanced verification mechanisms to bolster confidence among users. Hamrobazar's influence extends to fostering sustainability through the reuse and recycling of goods. By promoting the exchange of second-hand items, the platform aligns with global sustainability trends and encourages responsible consumer behavior.

Hamrobazar's niche approach addresses a specific market segment by facilitating direct interactions and promoting sustainability. Its role in promoting the reuse of goods and providing a platform for local transactions underscores its distinctive impact on Nepal's e-commerce landscape. [6]

2.2 Gap Analysis

In the previous state, the online shopping system suffered from slow page load times, a cluttered user interface, and a lack of mobile responsiveness. These shortcomings resulted in a less engaging and satisfying shopping experience for customers, compounded by the absence of essential features such as product comparisons. However, the current state of the online shopping system represents a significant improvement. Many of the previous issues have been addressed, and new features have been implemented to enhance the user experience. The current system boasts fast page load times, a clean and intuitive user interface, and full mobile responsiveness. Additionally, product comparison features have been integrated to enrich customer experiences.

Despite these notable improvements, some gaps still remain in the current system. Most notably, customers are not able to easily compare products side by side, which can hinder their decision-making process. Addressing this gap by incorporating a convenient and user-friendly product comparison functionality will further enhance the overall shopping experience and bridge the final divide in the system's capabilities. By continually striving to improve and refine these aspects, the online shopping system can offer a truly seamless and satisfying experience for its users.

2.3 Functional and Non-functional Requirements:

Functional requirement:

Functional requirements play a pivotal role in shaping the essence of a system or software application. These requirements delve into the specifics of how the system should function, capturing the essential behaviors and interactions it must exhibit to cater to user needs. By outlining the precise functions and features the system is expected to possess, functional requirements provide a roadmap that guides developers and designers in crafting a solution that aligns with user expectations.

These requirements serve as a bridge between the abstract concept of a system and its practical manifestation. They encapsulate the envisioned user experiences, detailing the step-by-step processes and functionalities that users will encounter. By articulating the system's capabilities in clear terms, functional requirements enable effective communication among stakeholders, ensuring everyone is on the same page regarding what the system will ultimately deliver. In essence, functional requirements are the tangible manifestation of the system's purpose,

offering a comprehensive understanding of its behavior and interactions, and acting as the foundation upon which the development process is constructed.

General Requirements for online shopping are:

- Speed,
- Friendliness,
- Ease of use in checkout flow,
- Personalization and
- Accessibility.

In our online shopping project, functional requirements outline what users can do on the website. This includes:

User Registration and Authentication

- Users can create accounts and log in securely.
- User authentication ensures only authorized users can access accounts.

Product Catalog

- A comprehensive product catalog is available.
- Products are categorized for easy navigation.

Product Details

- Users can view detailed information about products, including images, descriptions, prices, and availability.

Shopping Cart

- Users can add products to a cart for future purchase.
- Cart displays total cost and quantities of selected items.

Checkout and Payment

- Users can proceed to checkout from the cart.
- Payment options are supported, such as COD (cash on delivery) and online.

User Feedbacks

- Users can leave feedbacks for products.

Search

- Users can search for products by keywords.

Overall, it's about making sure the website works well, is easy to understand, and helps users find, buy and makes payment for the products comfortably.

Non-Functional Requirement:

Non-functional requirements, also known as quality attributes or system attributes, specify the characteristics and qualities that a system or software application should possess, beyond its specific functionality. Unlike functional requirements that focus on what the system does, non-functional requirements focus on how well the system performs its functions and the overall user experience. Non-functional requirements ensure that the system meets certain standards of quality, making sure it's efficient, reliable, and user-friendly in various aspects beyond just its primary functionalities. These requirements focus on aspects like performance, security, usability, reliability, scalability etc.

The non-functional requirements for our online shopping project encompass a range of essential aspects. In terms of performance, the system must adeptly handle numerous users concurrently, ensuring smooth operation even during peak usage times. Swift page loading is vital to create an uninterrupted shopping experience for users. Security is paramount, necessitating the encryption and secure storage of user data and payment information to maintain privacy and trust.

Usability is a core concern, requiring an intuitive and easily navigable user interface. Furthermore, the system should adapt seamlessly to different devices and screen sizes, enhancing accessibility. Reliability is upheld through continuous availability, with minimal downtime to assure users of consistent service. Backup and recovery mechanisms are also integral, safeguarding against data loss and system disruptions.

Scalability is essential for accommodating future growth, with the system designed to handle increased user traffic and the expansion of product offerings. Compatibility remains a focal point, requiring the system to function effectively across a variety of web browsers and operating systems, ensuring a cohesive experience for diverse users. These non-functional requirements collectively shape a robust, user-friendly, and adaptable online shopping platform.

In our online shopping project, non-functional requirements focus on how the website works rather than what it does. This means making sure the website loads quickly, is easy to use, and

looks good on different devices. It should also be secure, keeping user information safe, and handle many users at once without slowing down. These non-functional requirements ensure the website is reliable, fast, secure, and user-friendly for everyone who visits it.

2.4 Feasibility Study:

A feasibility study is an analysis that takes all of a project's relevant factors into account including economic, technical, legal, and scheduling considerations to ascertain the likelihood of completing the project successfully. It provides insights into the project's viability and potential challenges. [7]

In a feasibility study, a proposed plan or project is evaluated for its practicality. As part of a feasibility study, a project or venture is evaluated for its viability in order to determine whether it will be successful. As the name implies, a feasibility analysis is used to determine the viability of an idea, such as ensuring a project is legally and technically feasible as well as economically justifiable. It tells us whether a project is worth the investment in some cases, a project may not be doable. There can be many reasons for this, including requiring too many resources, which not only prevents those resources from performing other tasks but also may cost more than an organization would earn back by taking on a project that isn't profitable.

Advantages of Feasibility Studies:

- Resource Assessment: Feasibility studies provide a comprehensive overview of the resources currently available for the project. This includes human resources, financial capital, technology, and equipment. It helps identify gaps and potential needs for additional resources.
- Risk Identification: Through a feasibility study, potential challenges and risks can be identified early on. This allows project managers to develop strategies to mitigate or manage these risks effectively.
- Financial Viability: A feasibility study assesses the economic aspects of the project, including potential costs, revenue streams, and profitability. It helps in making informed decisions about whether the project is financially feasible.
- Project Scope: The study helps define the scope of the project, outlining the goals, objectives, and deliverables. This ensures that the project stays focused and aligned with its intended purpose.

- Decision-Making: The insights gained from a feasibility study empower decision-makers to make informed choices about proceeding with the project. It helps in avoiding investing resources in projects that are unlikely to succeed.
- Efficiency and Effectiveness: By identifying potential roadblocks and resource shortages, feasibility studies contribute to efficient project planning and allocation of resources.

Feasibility study includes:

Technical Feasibility:

Technical feasibility refers to the evaluation of whether a proposed project, system, or initiative can be successfully developed, implemented, and operated using the available technology and resources. It involves assessing whether the required hardware, software, and infrastructure are attainable and compatible, and if the project can function effectively within the existing technological environment. Technical feasibility is all about checking if our project can actually work from a technology standpoint. Let's see if our online shopping idea is a good fit for the tech world.

- Hardware Needs: We have smartly sorted out what tools and gear are required. Think computers and such to efficiently handle and safeguard data for our online shop.
- Software Essentials: Our strategy for software is spot-on. We have carefully picked the right computer programs to fuel our online shop's operations. Deciding which languages and systems to use was thoughtfully done.
- Establishing Online Presence: Our online presence is firm and strong, all thanks to a reliable and sturdy internet connection. It's been thoroughly checked and confirmed that it's solid and dependable.

To sum it up, we've tackled the technical side of things like pros. Hardware, software all have been nailed down. And our internet connection is rock-solid. This project's technical groundwork is set, ready to shine.

Operational Feasibility:

Operational feasibility refers to the evaluation of whether a proposed project or system can be effectively implemented and integrated into the existing operational environment of an organization. It involves assessing whether the project aligns with the organization's processes, culture, and resources, and whether it can function smoothly and deliver the intended benefits

once it is up and running. Operational feasibility steps into the real world to check if our project can smoothly function in practical terms.

- User-Friendly Experience: Our project takes the gold in operational feasibility by offering an easy-to-use interface. Anyone can hop on and use it without needing special training. The way things look, icons, and how you move around – it's all designed to be clear and simple.
- Reliable Data: We have made sure the info our system dishes out is accurate and trustworthy. The pieces we have put together work together like a charm to give you dependable results. This boosts confidence in the system.
- Timing for Data: We have thought through how often the system grabs and updates data. It's like balancing real-time updates with efficiency, so users get info without slowing things down.
- Data Management: Our plan for storing and handling data is solid. The collected info gets organized and stored smartly. This makes it easy to access and use for making decisions.

All in all, our online shopping project shines brightly when it comes to operational feasibility. The easy-to-use interface, solid data accuracy, smooth data collection, and smart data management combine for a system that's all set to work seamlessly and give users a great experience.

Economic Feasibility:

Economic feasibility serves as a practical financial assessment for a project, ensuring that it makes financial sense. It's like a reality check for the money matters. We dive into both the project's potential costs and earnings to gauge if it's a financially sound decision. If the projected earnings outweigh the costs, we're good to go.

- Target Market: It's like figuring out who might like what we are offering. For our online shopping idea, we're thinking about people who want to shop online easily.
- Market Size: Here, we are guessing how many people might want to use our online shopping thing. We are checking if enough people are interested to make it a good idea.
- Competitive Landscape: It's like sizing up the competition in the field. We have looked into other online shops to grasp their strategies, pricing, and market presence. This helps us position ourselves effectively.

In terms of finances, our project holds promise. It's a cost-effective endeavor we are mainly talking about a basic computer and internet access. These expenses are quite manageable. So, when we weigh this against the potential earnings, our project appears to be a smart and practical choice. It's like a budget-friendly option that's poised for success.

Legal Feasibility:

Legal feasibility refers to the assessment of whether a proposed project or initiative can be carried out in compliance with relevant laws, regulations, and legal constraints. It involves evaluating the potential legal risks, implications, and requirements associated with the project. Legal feasibility assesses whether our project aligns with the legal and regulatory landscape, ensuring that we're on the right side of the law.

- Laws and Regulations: We have carefully examined the laws and regulations that apply to our online shopping project. This includes consumer protection, data privacy, intellectual property, and other relevant areas.
- Compliance: Our project is structured to adhere to all applicable laws. We have made sure that our operations, data handling, and user interactions are in line with legal requirements.
- Terms and Conditions: Our project is equipped with clear and transparent terms and conditions that users need to agree to. This ensures that users understand the rules and policies governing their interaction with the system.

In essence, our project stands strong on the legal front. We have done our homework to ensure that our online shopping venture is compliant with the law, respects user rights, and operates within the legal boundaries.

Scheduling Feasibility:

Scheduling feasibility refers to the evaluation of whether a proposed project or initiative can be realistically completed within a specified timeframe. Scheduling feasibility evaluates whether our project can be completed within the allotted time frame, considering the available resources and potential constraints.

- Project Timeline: We have devised a realistic timeline for our online shopping project, factoring in tasks, milestones, and dependencies. This timeline aligns with the project's scope and objectives.

- Resource Allocation: We have allocated the necessary resources, including human resources, tools, and equipment, in a way that supports the planned schedule. This ensures that we have what we need to stay on track.
- Dependencies: We have identified any tasks or activities that are dependent on each other and organized them accordingly. This helps prevent bottlenecks and delays.
- Risk Management: Our scheduling plan includes a strategy for handling potential delays or setbacks. We have considered possible risks and have contingency plans in place to mitigate their impact on the schedule.

Overall, our project's scheduling feasibility is robust. We have crafted a well-thought-out timeline, allocated resources sensibly, managed dependencies, and prepared for potential challenges. This positions us to execute the project within the set timeframe successfully.

In summary, the online shopping system is technically user-friendly, operationally designed for e-commerce efficiency, economically and legally feasible with minimal financial requirements.

Chapter 3: System Design and Methodology

3.1 SDLC Model:

Software Development Life Cycle (SDLC) is a process used by the software industry to design, develop and test high quality software. The SDLC aims to produce high-quality software that meets or exceeds customer expectations, reaches completion within times and cost estimates.

- SDLC is the acronym of Software Development Life Cycle.
- It is also called as Software Development Process.
- SDLC is a framework defining tasks performed at each step in the software development process.
- ISO/IEC 12207 is an international standard for software life-cycle processes. It aims to be the standard that defines all the tasks required for developing and maintaining software.[8]

The following figure is a graphical representation of the various stages of a typical SDLC.

Figure 1: SDLC (source: <https://www.tutorialspoint.com/sdlc/sdlcmodel>)

In general, an SDLC methodology follows these following steps:

- Analysis: The existing system is evaluated. Deficiencies are identified. This can be done by interviewing users of the system and consulting with support personnel.
- Plan and requirements: The new system requirements are defined. In particular, the deficiencies in the existing system must be addressed with specific proposals for improvement. Other factors defined include needed features, functions and capabilities.
- Design: The proposed system is designed. Plans are laid out concerning the physical construction, hardware, operating systems, programming, communications and security issues.
- Development: The new system is developed. The new components and programs must be obtained and installed. Users of the system must be trained in its use.
- Testing: All aspects of performance must be tested. If necessary, adjustments must be made at this stage. Tests performed by quality assurance (QA) teams may include systems integration and system testing.
- Deployment: The system is incorporated in a production environment. This can be done in various ways. The new system can be phased in, according to application or location, and the old system gradually replaced. In some cases, it may be more cost-effective to shut down the old system and implement the new system all at once.
- Upkeep and maintenance: This step involves changing and updating the system once it is in place. Hardware or software may need to be upgraded, replaced or changed in some way to better fit the needs of the end-users continuously. Users of the system should be kept up-to-date concerning the latest modifications and procedures.

SDLC Models

There are various software development life cycle models defined and designed which are followed during the software development process. These models are also referred as Software Development Process Models". Each process model follows a Series of steps unique to its type to ensure success in the process of software development. [10]

Following are the most important and popular SDLC models followed in the industry –

- Waterfall Model
- Iterative Model

- Spiral Model
- V-Model
- Big Bang Model

3.1.1 Used Model:

Among these models, we used iterative model in our project.

In the Iterative model, iterative process starts with a simple implementation of a small set of the software requirements and iteratively enhances the evolving versions until the complete system is implemented and ready to be deployed. An iterative life cycle model does not attempt to start with a full specification of requirements. Instead, development begins by specifying and implementing just part of the software, which is then reviewed to identify further requirements. This process is then repeated, producing a new version of the software at the end of each iteration of the model. The Iterative Model allows the accessing earlier phases, in which the variations made respectively. The final output of the project renewed at the end of the Software Development Life Cycle (SDLC) process. [8]

Figure 2: Iterative model (Source: https://www.tutorialspoint.com/sdlc/sdlc_iterative_model.htm)

The various phases of Iterative model are as follows:

- Requirement gathering & analysis: In this phase, requirements are gathered from customers and check by an analyst whether requirements will fulfill or not. Analyst checks that need will achieve within budget or not. After all of this, the software team skips to the next phase.
- Design: In the design phase, team design the software by the different diagrams like Data Flow diagram, activity diagram, class diagram, state transition diagram, etc.
- Testing: After completing the coding phase, software testing starts using different test methods. There are many test methods, but the most common are white box, black box, and grey box test methods.
- Implementation: In the implementation, requirements are written in the coding language and transformed into computer programmers which are called Software.

Advantages (Pros) of Iterative Model:

- Testing and debugging during smaller iteration is easy.
- A Parallel development can plan.
- It is easily acceptable to ever-changing needs of the project.
- Risks are identified and resolved during iteration.
- Limited time spent on documentation and extra time on designing.

Application Scenario: Operating system development:

Imagine creating an operating system development using the iterative model:

In the context of operating system development, the iterative model can be applied to various scenarios to ensure the development of a robust and functional operating system. Here's an application scenario of the iterative model in operating system development:

- Initial Planning and Design (Iteration 1): In this phase, the high-level requirements for the new operating system are gathered and analyzed. The initial design of the core components, such as process management, memory management, and file system, is outlined. A basic prototype of the operating system is developed with minimal features.
- Implementation and Testing (Iteration 2): The prototype developed in the first iteration is implemented with the basic features. This includes writing code for process

scheduling, memory allocation, basic I/O operations, and other fundamental functionalities. The developed code is thoroughly tested to identify and fix bugs.

- Enhancement and Refinement (Iteration 3): In this phase, feedback from testing is used to refine the existing features and add additional functionalities. For example, the process scheduling algorithm might be improved for better performance, memory management might be extended to support virtual memory, and more device drivers might be added to support various hardware components.
- Security and Performance Assessment (Iteration 4): This iteration focuses on assessing the security and performance aspects of the operating system. Security mechanisms like access control, authentication, and encryption are added or strengthened. Performance bottlenecks are identified and optimized.
- User Interface and User Experience (Iteration 5): The operating system's user interface is developed or refined to ensure a user-friendly experience. Graphical elements, system notifications, and user interaction mechanisms are improved based on user feedback and usability studies.
- Compatibility and Integration (Iteration 6): The operating system is tested for compatibility with a wider range of hardware configurations and software applications. Compatibility issues are addressed, and integration with third-party software is tested.
- Stability and Reliability (Iteration 7): The focus of this iteration is on improving the overall stability and reliability of the operating system. Rigorous testing and debugging are performed to ensure that the system can handle a variety of scenarios without crashing or malfunctioning.
- Finalization and Deployment (Iteration 8): The operating system is polished, and all major features are fully implemented. The system undergoes extensive testing, including stress testing and performance benchmarking. Once the operating system meets the predefined quality standards, it is ready for deployment.

By applying the iterative model to operating system development, developers can ensure that the operating system evolves over time, incorporating user feedback, addressing issues, and adapting to changing hardware and software landscapes. This approach also allows for flexibility in responding to emerging requirements and technologies.

Why is this model used?

We use iterative model in our online shopping system project due to its inherent compatibility with the project's goals and complexities. Given the evolving nature of customer preferences and the dynamic online shopping landscape, an iterative approach aligns seamlessly with the need for continuous adaptation. This model allows us to begin with a basic implementation of essential features, addressing immediate requirements and establishing a functional foundation. As the iterations progress, we can systematically incorporate additional features, such as secure payment processing, user-friendly interfaces, and efficient product delivery mechanisms. This incremental approach is vital in enhancing user experience, addressing security concerns, and refining technical functionalities. The iterative model's iterative nature, emphasizing user feedback and constant refinement, will enable us to address potential gaps identified in our gap analysis, such as fragmented shopping experiences and challenges related to security and product quality. By iteratively building and improving the system, we ensure that our online shopping platform remains adaptable, competitive, and aligned with customer expectations, ultimately leading to a reliable, user-friendly, and efficient solution.

3.2 Context diagram

Context diagram is a diagram that defines the scope and boundary for the systems. It describes the highest level view of a system. It summarizes all the processing activities within the system in a single process symbol.

At the core of a context diagram is the central system or application under scrutiny. This system is positioned at the center of the diagram, signifying its importance. Surrounding this central system are external entities, which can take the form of users, other systems, databases, or any external element that communicates with the system. These external entities are key participants in the system's operation and influence its behavior.

The interactions between the central system and external entities are depicted through arrows called data flows. These data flows visualize the exchange of information or data between the system and the external entities. The direction of the arrows indicates the flow of data, showcasing how information is transmitted between the central system and its external counterparts.

Context diagrams are particularly useful during the early stages of system analysis and design. They provide a clear visual snapshot of the system's external interactions, making it easier to identify key stakeholders, understand data exchange, and define the scope of the system. As

projects progress, context diagrams serve as a foundation for creating more detailed DFDs that explore the internal processes within the system.

Some of the benefits of a Context Diagram are:

- Shows the scope and boundaries of a system at a glance including the other systems that interface with it
- No technical knowledge is assumed or required to understand the diagram
- Easy to draw and amend due to its limited notation
- Easy to expand by adding different levels of DFDs
- Can benefit a wide audience including stakeholders, business analyst, data analysts, developers

Figure 3: Context diagram of Online shopping system

The above shown diagram is the context diagram of online shopping system. It consists of three entities i.e. Admin, Customer and Delivery Person which interacts with each other through a common system, online shopping system. Here Customer Admin and delivery person all three gives login and registration details to the system. The system checks if the given details are

valid or invalid and gives confirmation to customer admin and delivery person. Admin manages details related to items and orders, admin also view the sales report. Customer search various items available and places order where system provide order details to the system then the payment process is proceed which is confirmed by the system. Whereas delivery person receives delivery details, delivers the orders after receiving verification code from the system.

3.3 Data flow Diagram (DFD)

In this diagram, a single main process of the context diagram is broken down into two or more process of the system. It shows overall processes of the system.

DFDs are commonly used in systems analysis and design to visualize the flow of data, processes, and interactions among various components of a system. They provide a clear and structured way to understand how data moves through a system and how it is processed.

DFDs consist of several components:

- **Processes:** Processes are represented as circles or ovals and represent the transformations or actions that occur within the system. Each process takes inputs, performs some action or manipulation, and produces outputs. Processes can be anything from calculations and data transformations to complex algorithms or actions.
- **Data Flows:** Data flows are represented as arrows and depict the movement of data between processes, external entities, and data stores. They show how data is passed from one component to another, indicating the direction of data flow.
- **External Entities:** External entities are entities outside the system that interact with it. These can include users, external systems, or organizations. External entities send inputs to the system and receive outputs from it.
- **Data Stores:** Data stores are repositories where data is stored persistently. They are represented as rectangles with two parallel lines at the top. Data stores can include databases, files, or any other data storage mechanism.

DFDs come in different levels of detail, ranging from the high-level Context Diagram (level 0) to more detailed levels that break down processes into sub-processes and interactions. DFDs are commonly used in systems analysis and design to model how a system functions and to communicate complex processes in a clear and organized manner.

DFD rules and tips

- Each process should have at least one input and an output.
- Each data store should have at least one data flow in and one data flow out.

- Data stored in a system must go through a process.
- All processes in a DFD go to another process or a data store.

Level 0 DFD

The Level 0 Data Flow Diagram (DFD) is an extension of the context diagram that provides a more detailed view of the processes within the system and the interactions between them and external entities. It breaks down the main processes and data flows that were shown in the context diagram into more detailed components.

In a Level 0 DFD:

- **Main Process:** The system itself is represented as a single process, often depicted as a circle or a bubble at the center of the diagram. This process corresponds to the entire system or application being analyzed.
- **External Entities:** These are the entities that interact with the system but are not part of it. They can include users, customers, other systems, or data sources. External entities are typically represented as squares or rectangles surrounding the main process.
- **Data Flows:** Arrows connect the external entities to the main process, depicting the flow of data between them. These data flows indicate the inputs and outputs to and from the system.

The Level 0 DFD is a foundational diagram that sets the stage for creating more detailed DFDs. While it doesn't illustrate the internal processes of the system, it's an essential starting point for understanding how data enters and exits the system and identifying key external entities.

Figure 4: Level-0 DFD of Online shopping system

Above figure shows Data-Flow Diagram (DFD) for our system. Our system has three entities, nine processes and five databases.

Description of processes:

Registration/Login:

Registration/Login part of the system is responsible for checking the validity of user. This process is done by both Customer, Delivery Person and Admin. When Admin, Delivery Person and Customer request for Registration, system asks for user information like username, address, phone number and other identification details. When the system declares them valid, all the information are stored in database. Then, user will be able to login using their username and password. When Customer, Delivery Person and Admin request for Login and provide their username and password, the process checks the database D1 to verify whether the entered username and password match registered information. If the entered information is valid, process is executed successfully and homepage for the user is displayed. If the entered information is not valid, process cannot be executed successfully and alert to enter valid information is displayed.

Manage Category:

Manage Category part of the system is accessed by Admin to add and edit products for sale. Admin can view product details in database D2 through system and according to that Admin can choose to add product or edit product or both. When addition or edition is done system will confirm back to Admin.

Search Product:

Search product part of the system is responsible for helping Customer and Admin search products that are available for sale. When Admin and Customer requests for this process, system links to database D2 and whole database is searched. When required keywords are matched database will send response to system and system in return will show relevant products.

Order:

When Customer places order, system looks for the product in database D2. D2 provides details about the product details and checks whether the requested products are available. When the

order is successfully placed, the orders are placed in database D3. Admin can also request the system about the availability of the product through D2.

Manage Order:

Manage Order part of the system is be responsible for managing and directing orders. This part is only accessible by Admin. Admin can cancel orders, disable order when products are limited and update ordering process. When Admin requests access to manage order, the process check database D3. D3 contains orders details which is send to the process as response. Process then displays list of orders and details to Admin as its response. Then Admin can manage and edit the ordering and transitioning system.

Payment:

Payment part of the system is responsible for payment related functioning of the system. When customer request payment details, the details are requested to database D3. When payments are done, systems gives confirmation to customer.

Delivery:

Admin selects which delivery person will deliver the products. Delivery person gets the details of the order from database D3 through the system. Delivery person gives verification code confirming the delivery status. The delivery details are stored in database D4.

Sales report:

Sales Report is responsible for providing all the reports to the system. Admin previews purchases and system confirms with details.

Feedback:

Feedback helps Admin keep track of customer satisfaction. Customer gives feedback and feedbacks are stored in database D5. Admin can view feedbacks from database through the system.

Level-1 DFD:

A Level 1 Data Flow Diagram (DFD) is the next level of detail that follows the Context Diagram (Level 0 DFD). It breaks down the processes identified in the Context Diagram into smaller subprocesses, offering a more detailed view of how data flows within the system. A Level 1 DFD provides a closer look at the interactions between processes, data stores, and external entities, helping to refine the understanding of the system's functionality.

In a Level 1 DFD:

- **Main Process (From Level 0):** The main process from the Level 0 DFD becomes the central focus of the Level 1 DFD. This process is further divided into subprocesses, each of which represents a specific task or activity within the system.
- **Subprocesses:** The main process is broken down into smaller subprocesses, each depicted as a separate process symbol (rectangle). These subprocesses represent more detailed actions that take place within the system. Data flows between these subprocesses, external entities, and data stores.
- **External Entities (From Level 0):** External entities remain in the Level 1 DFD and continue to interact with the system's subprocesses. Data flows between the external entities and the subprocesses they interact with.
- **Data Flows:** Data flows that were introduced in the Level 0 DFD are further refined at this level. They illustrate the movement of data between subprocesses, data stores, and external entities. The direction of data flow is indicated by arrows.
- **Data Stores:** Data stores introduced in the Context Diagram can be detailed further at this level, showing how data is stored and retrieved within the system's subprocesses.

A Level 1 DFD provides a more comprehensive understanding of the system's internal processes compared to the Context Diagram. It's useful for uncovering the sequence of actions, data transformations, and interactions that occur within the system. As projects become more complex, multiple levels of DFDs can be created to break down subprocesses into even finer levels of detail. This hierarchical approach helps ensure a thorough analysis of the system's functionality and interactions.

Figure 5: Level-1 DFD of Manage category of Online shopping system

Here is the diagram of level-1 DFD of manage category. Sub categories and product are two sub processes. Admin can add, edit and delete product in manage category and data are stored in D2 database. Similarly, Admin can add, edit and delete product in this sub categories and product and data are stored in database D2.1 and database D2.2 respectively.

3.4 Entity-Relation Diagram

ER diagram is a graphical representation of an Entity-Relationship model. It is expressed in terms of entities, attributes and relationships. It is a graphical representation of the database's structure, showcasing how entities are related to each other and how data flows between them. ER diagrams are widely used in database design and system analysis to illustrate the logical structure of a database system. Its purpose is to capture the richest possible understanding of the meaning of data necessary for an information system or organization.

Key components of an ER diagram include:

- **Entities:** Entities are objects or concepts with distinct attributes that are stored in a database
- **Attributes:** Attributes are properties or characteristics of entities. In an ER diagram, attributes are represented as ovals connected to their respective entities.
- **Relationships:** Relationships represent how entities are connected or associated with one another. They describe the associations between entities and add context to the data model. Relationships are represented by diamond shapes and lines connecting entities.
- **Cardinality:** Cardinality specifies the number of instances of one entity that can be associated with the instances of another entity. It helps define the nature of the relationship, whether it's one-to-one, one-to-many, or many-to-many.
- **Primary Keys:** A primary key uniquely identifies each instance of an entity. It's a critical component for maintaining data integrity and ensuring data uniqueness.
- **Foreign Keys:** A foreign key is a reference to the primary key of another entity. It's used to establish relationships between entities.

ER diagrams provide a visual and intuitive way to communicate complex database structures. They aid in database design by assisting in the identification of entities, attributes, and relationships, which in turn helps in creating a well-organized and efficient database schema. ER diagrams are often created using specialized software or drawing tools and are an essential step in the database design process.

Figure 6: ER diagram of Online shopping system

The given ER diagram of Online shopping system shows relationship between the entities: Customer, Admin, Category, Product, Cart, Order, Sales report, Delivery person, Delivery, Feedback, Payment and Transaction. Here, customer id, admin id, category id, product id, trans id, order id, delivery of, feedback id, pay id, sales id and cart id are the primary keys for customer, admin, products, transactions, order, delivery person ,feedback, payment, sales report and cart entities respectively. Similarly, customer id, order id and product id are foreign key for payment entity. Admin manages category by adding product and edit the product available. Admin views sales report and transaction. Admin assigns delivery of orders to delivery person and checks for payment .Similarly Category has product which are placed to cart whereas Customer views the product and places or adds the product in the cart then the cart is placed for order. The order is given for delivery to delivery person and also payment is done through COD (Cash On Delivery) or online i.e. khalti using internet where payment have many transactions where order also confirms transaction. Admin also checks feedback that are provided by customer.

3.5 Use case Diagram

Use case diagram summarizes the details of a system's user also known as actors and their interaction with the system. They focus on "what" the system does from a user's perspective rather than "how" it does it. It consists of use cases and actors. Use case diagrams provide an overview of the functional requirements of a system from a user's perspective. Use Case Diagrams help to depict the different ways users interact with the system, highlighting the functionalities the system provides.

Key elements of a Use Case Diagram include:

- **Actors:** Actors are external entities that interact with the system. They can be users, other systems, or even hardware devices. Actors initiate use cases (actions) within the system. Actors are represented as stick figures.
- **Use Cases:** A use case represents a specific interaction or scenario between an actor and the system. Each use case describes a particular functionality or goal the system provides to users. Use cases are represented as ovals.
- **Associations:** Associations are lines connecting actors and use cases, indicating that an actor interacts with a specific use case. Associations show the roles of actors in the use case scenarios.
- **System Boundary:** The boundary of the system defines what's inside the system and what's outside (actors). This boundary helps clarify the scope of the system.

Figure 7: Usecase diagram of Online shopping system

We have three actors in our use case diagram Admin, Customer and Delivery Person.

Admin can register and login, search products and manage product categories, view order details and manage orders, access payment details, sales reports, and get feedbacks. Customer can register, login, access their order details, make payments, leave feedbacks, and search for products using keywords. Delivery person can login and deliver products.

Chapter 4: Implementation

4.1 Hardware and Software Requirements:

For the successful implementation of our online shopping system, specific hardware and software requirements need to be met.

Hardware requirements:

On the hardware side, a robust server is essential to host the website, handling user requests and database queries efficiently. A dedicated database server is necessary to store product details, user information, and transaction records securely. A reliable and high-speed network connection ensures seamless communication between users and the server. For scalability, a load balancer may be considered to distribute traffic evenly across multiple servers. Additionally, a backup and recovery system is crucial to safeguard data integrity and ensure system availability in case of failures.

Hardware requirements for an online shopping system play a vital role in ensuring the system's efficiency, reliability, and overall user experience. This dynamic and transaction-intensive environment necessitates hardware that can handle user traffic, process data, and facilitate seamless interactions. Several key considerations are involved in determining the appropriate hardware setup for an online shopping system.

To ensure that our online shopping system operates efficiently and provides users with a seamless shopping experience, the following hardware specifications are crucial:

- Memory (RAM): A minimum of 8 GB of RAM is essential. This memory capacity enables the system to handle concurrent user interactions, such as browsing product listings, managing shopping carts, and processing orders.
- Operating System: The online shopping system is designed to work seamlessly on Windows operating systems, particularly Windows 10 or later versions. Compatibility with these versions ensures optimal performance and functionality.
- Physical Memory: Device's physical memory, often referred to as RAM, plays a critical role in the system's responsiveness. With 16.0 GB of installed RAM (15.8 GB usable), device offers a substantial memory capacity to support smooth multitasking and data processing.
- Database Compatibility: The online shopping system is engineered to seamlessly integrate with modern relational databases. Compatibility with databases such as MySQL, PostgreSQL, or Microsoft SQL Server is recommended for efficient data storage, retrieval, and management.

By meeting these hardware specifications, users ensure that their devices possess the capabilities required for the online shopping system's optimal operation. The recommended RAM and database compatibility contribute to efficient multitasking, seamless data processing, and a satisfying shopping experience. Additionally, compatibility with Windows operating systems ensures that users can effortlessly access and navigate the platform while enjoying its full functionality.

In conclusion, hardware requirements for an online shopping system must address the platform's dynamic nature, high user interaction, and data-intensive processes. The right combination of CPU power, RAM, storage, networking capabilities, redundancy mechanisms, and security features is pivotal in delivering a seamless, secure, and satisfying online shopping experience for users.

Software requirements:

Software requirements for an online shopping system are like a shopping list of programs that the system needs to work properly. These include things like the operating system that runs the system, special software to manage the website, databases to store products and user data, coding languages to make everything function, and security tools to keep things safe. It's basically a set of tools and programs that work together to create the online shopping experience you see on the website. A reliable database management system (DBMS) like MySQL is crucial for data storage and retrieval. Programming languages like PHP, HTML, CSS, JavaScript, form the foundation of the system's logic and user interface.

- PHP (Hypertext Preprocessor): PHP is a server-side scripting language that is commonly used for web development. It excels in creating dynamic and interactive web pages. When a user requests a web page, the PHP code is executed on the server before the page is sent to the user's browser, allowing for the generation of content on-the-fly. PHP is especially suited for web applications and websites that require real-time data processing, user authentication, and dynamic content generation. It is open-source, widely adopted, and known for its versatility in seamlessly integrating with databases and other technologies.
- HTML (Hypertext Markup Language): HTML is a fundamental language for creating and structuring content on the web. It is not a programming language but a markup language that uses a syntax of tags and elements to define the structure of a web page. HTML provides the foundation for presenting text, images, links, and other multimedia

elements on a website. It's the backbone of the web, allowing developers to arrange content in a hierarchical manner and create hyperlinks for navigation.

- CSS (Cascading Style Sheets): CSS is a stylesheet language used to control the visual presentation and layout of HTML documents. It separates the content and structure of a webpage from its design and appearance. By defining styles for various HTML elements, developers can achieve consistent fonts, colors, spacing, and positioning across multiple web pages. CSS enables the creation of responsive designs that adapt to different screen sizes and devices, enhancing the user experience.
- JavaScript: JavaScript is a versatile programming language that plays a crucial role in web development. It's primarily used on the client side, meaning it's executed within the user's web browser. JavaScript enables developers to create interactive and dynamic elements on web pages, such as animations, form validation, and pop-up notifications. It's also heavily used in building web applications, enabling asynchronous communication with servers (AJAX) and enhancing user interfaces with modern frameworks like React, Angular, and Vue.js.
- MySQL: MySQL is a widely used open-source relational database management system (RDBMS). It provides a structured and efficient way to store and manage data. MySQL employs the Structured Query Language (SQL) to create, retrieve, update, and delete data in a database. It's particularly well-suited for web applications that require efficient data storage and retrieval. With features like data integrity, indexing, and transactions, MySQL ensures the reliability and consistency of data in web applications.

In conclusion, the software requirements of an online shopping system compose a dynamic ensemble of components. From operating systems to content management systems, programming languages, databases, and security measures, each piece contributes to creating an engaging, functional, and secure online shopping experience for users. The harmonious interplay of these software elements is what enables seamless navigation, efficient transactions, and enjoyable interactions on an online shopping platform.

4.1.1 Language Used:

Online shopping system projects typically involve a combination of programming languages to build both the frontend and backend components of the system. Here are some commonly used languages

Frontend Languages:

- HTML (Hypertext Markup Language): HTML forms the foundation of web pages by structuring content. It defines headings, paragraphs, images, links, and more. We have utilized HTML to ensure a well-organized and informative layout for displaying products, descriptions, and user interactions.
- CSS (Cascading Style Sheets): CSS brings life to web pages by adding visual appeal. We have applied CSS to style fonts, colors, spacing, and the overall design, creating an inviting and user-friendly interface that enhances the shopping experience.
- JavaScript: JavaScript adds interactivity to the platform. It enables real-time updates, dynamic content loading, and responsive features. By using JavaScript, we have empowered users to interact with elements like shopping carts, search filters, and product previews.

Backend Languages:

- PHP: PHP serves as the backbone of our system's backend operations, encompassing data processing, server-side logic, and interactions with the database. We have utilized PHP to manage user inputs, process transactions, and interact with the database to ensure smooth operations behind the scenes.

Database Query Languages:

- SQL (Structured Query Language): SQL acts as the bridge between your application and the database. We have skillfully used SQL queries to manage, retrieve, and update data stored in the system's database, ensuring accurate product information and user records.

By skillfully utilizing these languages, we have created a platform that offers a smooth, and responsive shopping experience for users.

4.2 Testing:

Testing is the process of evaluating a system or its component(s) with the intent to find whether it satisfies the specified requirements or not. In simple words, testing is executing a system in order to identify any gaps, errors, or missing requirements in contrary to the actual requirements. [11]

The main purpose of testing is to detect errors. Testing must be thorough and well-planned. A partially tested system is as bad as an untested system and the price of an untested and under tested system is high. The implementation is the final and important phase. It involves user-training, system testing in order to ensure successful running of the proposed system. The user tests the system and changes are made according to their needs. The testing involves the testing of the developed system using various kinds of data. While testing, errors are noted and correctness is the mode.

Testing schemes refer to the strategies and plans implemented to evaluate the quality and functionality of a software system. They involve various testing techniques and approaches to ensure that the software meets its intended requirements and performs as expected. It consists of functional and non-functional testing.

Functional testing:

Functional testing focuses on verifying that the system's functionalities work correctly. It includes Unit testing, Integration testing, System testing and Beta testing.

Unit testing:

It is a type of software testing where individual units or components of software are tested. This is known as module testing. The modules are tested separately. The test is carried out during programming stage itself. In this step, each module is found to be working satisfactory as regards to the expected output from the module. The purpose is to validate that each unit of the software code performs as expected. It is done during the development (coding phase) of an application by the developers. There are numbers of reason in support of unit testing:

The size of the module single module is small that we can locate an error fairly easily.

The module is small enough that we can attempt to test it in some demonstrably exhaustive fashion.

Confusing interactions of multiple errors in widely different parts of software are eliminated. There are problems associated with testing a module in isolation. How so we run a module without anything to call it, to be called by it, possibly to output intermediate values obtained during execution? One approach is to construct an appropriate driver routine to call it and simply stubs to be called by it and to insert output statements in it. Stubs serves to replace modules that are subordinate to module to be tested. A stub or dummy subprogram uses the subordinate module's interface, may do minimal data manipulation, prints verification of entry and returns.

In the context of our online shopping system, consider the "Add to Cart" functionality as a module. During unit testing, this module is tested independently to ensure it works correctly. Through this unit test, the "Add to Cart" module is examined to confirm its functionality before integration with the broader online shopping system. This validation ensures that users can reliably add products to their carts, enhancing their overall shopping experience.

Integration testing

Integration testing signifies a pivotal stage in the software development process. It focuses on evaluating the harmonious operation of integrated components within the software. This level of testing is concerned with verifying that the entire system operates cohesively, satisfying both functional and non-functional requirements. Integration testing is geared towards validating the seamless interaction between various elements, ensuring that they collectively function as a unified whole. By conducting a series of systematic assessments, this phase prepares the proposed system for the subsequent user acceptance testing, confirming its readiness for real-world deployment.

In the context of our online shopping system, consider the integration testing for the "Checkout Process," which involves multiple integrated components like user adding products to the cart, proceeding to checkout, and entering valid payment details.

There are three types of integration testing:

Top Down Approach:

In the Top Down integration approach, software modules are integrated starting from the highest-level modules and gradually moving down the hierarchy. The main idea is to begin with the main control module (usually the highest level of the hierarchy) and then integrate its subordinate modules step by step. This process continues until all modules are integrated to create a complete system.

Bottom Up Approach:

Conversely, the Bottom Up integration approach begins with the lowest-level modules and gradually builds upwards, integrating higher-level modules as you progress. This strategy focuses on creating a strong foundation and addressing low-level functionality first before moving on to more complex interactions

Sandwich Strategy:

The Sandwich integration approach combines elements of both Top Down and Bottom Up strategies. In this method, integration starts from both the highest and lowest levels of the hierarchy simultaneously, with the goal of meeting in the middle. As the integrations move towards the center, they meet and "sandwich" the modules that are yet to be integrated.

Each approach has its advantages and considerations:

- **Top Down:** It's great for identifying architectural issues early, but it might not uncover low-level bugs until later stages.
- **Bottom Up:** It's effective at addressing low-level issues early, but higher-level architectural problems might not be apparent until later.
- **Sandwich:** It combines the benefits of both approaches, but it can be more complex to manage due to the simultaneous integration from both ends.

The choice of integration strategy often depends on the specific project's requirements, complexity, and the team's familiarity with the software architecture. Some projects might even use a combination of these strategies at different stages to optimize the integration process.

System testing

System testing is the stage of implementation. It is a level of testing that validates the complete and fully integrated software product. It is concerned with validating that the entire system meets its functional and non-functional requirements. The purpose of a system test is to evaluate the end-to-end system specifications. A series of tests are performed for the proposed system is ready for user acceptance testing. System testing helps to identify and fix defects before the system goes live. It validates that the system meets business requirements. Enhance user satisfaction by delivering a reliable and user friendly system. Ensures the system's performance and security under various conditions.

System testing is a critical phase of software development that ensures the online shopping system is thoroughly tested and ready for deployment. It involves various types of testing to cover different aspects of the system's functionality, usability, performance and security.

In the context of our online shopping system, let's consider the system testing scenario for the "Order Fulfillment" process, which involves various integrated functionalities like product catalog, shopping cart, payment processing, order confirming and delivery. This includes user selecting products, adding them to the cart, proceeding to payment, and confirming the order and delivery.

System testing involves black box and white box testing for testing the online shopping system operation.

White Box Testing in System testing:

White box testing, also known as clear box testing, is involved in system testing to examine the internal structure and logic of the software system. Testers with knowledge of the system's code and architecture use this approach to verify that individual code units and components work as expected. They analyze different code paths, logic flows, and algorithms to ensure correctness.

Example: In an online shopping system, white box testing during system testing might involve checking if the discount calculation logic is functioning correctly by analyzing the code that handles discounts and promotions.

Black Box Testing in System testing:

Black box testing is involved in system testing to evaluate the overall functionality of the system from an external user's perspective. Testers approach the system without knowledge of its internal code and structure. They interact with the user interface and input various scenarios to identify defects related to user experience, input validation, and system requirements.

Example: During black box testing in an online shopping system, testers would go through the entire purchasing process from item selection to payment. They would ensure that users can easily navigate, add products to their cart, proceed to checkout and successfully complete a Purchase.

Beta testing:

Beta testing is an opportunity for real users to use a product in a productive environment to uncover any bugs or issues before a general release.

Beta testing is the final round of testing before releasing a product to a wide audience. This objective is to uncover as many bugs or usability issues as possible in this controlled setting. Closed beta testing is used as a testing phase in our online shopping system. Closed beta testing occurs after alpha testing and before the system is opened to a wider audience in the beta testing phase. Closed beta testing involves releasing the system to a selected group of external users who are not part of the development team. These users are often chosen based on specific criteria, such as demographics, interests, or expertise. The testing group is smaller and more focused than the general public in the beta testing phase. Developers can make adjustments based on the feedback received during closed beta testing before the system enters the broader beta testing phase or is officially launched. It provides an additional layer of feedback and testing before the system is exposed to a wider audience.

Non Functional testing:

Non-functional testing in an online shopping system involves evaluating aspects beyond specific functionalities that affect the overall user experience performance, and quality of the system. An excellent example of non-functional testing would be to check how many people can simultaneously login into a software. Non-functional testing is equally as important as functional testing and affects client satisfaction.

It includes:

Performance testing: It focuses on assisting system responsiveness and speed under different user's loads. It includes load testing, stress testing, and scalability testing. Performance testing ensures that it can handle peak user traffic without slowing down or crashing during high demand periods, like seasonal sales.

Security testing: It examines the vulnerabilities in the system that could lead to unauthorized access data breaches, or other security threats. It involves testing for issues like SQL injection, cross-site scripting and data encryption. It also helps to ensures costumer data remains secure and financial transactions are protected.

Usability testing: It evaluates the user-friendly and intuitive the user interface. Usability testing involves real users interacting with the system to identify navigation difficulties and user experience issues. It helps to ensures that users can easily browse products, add them to carts, and complete purchase without confusion.

Reliability testing: It focuses on assessing the system's stability and ability to perform consistently. Includes testing for the system crashes, error recovery and data integrity. It ensures that system operates reliably without unexpected failures that could disrupts user experiences.

Compatibility testing: It checks how well the system performs across different devices, browser and operating system. It helps to ensure that the users can access and use the online shopping platform regardless of their preferred technology.

Accessibility testing: It evaluates the system's compatibility to handle with assistive technologies, making it usable for people with disabilities. It ensures that the system follows accessibility guidelines and can be accessed by a wider range of users.

Scalability testing: It helps to assess the system's ability to handle increased workload and user interactions as the user base grows. It ensures that the system can easily be expanded to accommodate more users without compromising performance.

Availability testing: It checks system's uptime and availability to users. It makes sure that the system remains accessible and operational, minimizing downtime that could affect users shopping experience.

4.3 Test Cases

Test Case: 1

Table 1. User (Admin and Customer) Login and Registration

S.no	Test case	Input	Expected result	Actual result	Status
1	User Registration	New user details (name, email, etc.)	User account is created successfully	User account created successfully	Success
2	User Login	Valid login credentials	User is logged into the system	User logged in successfully	Success
3	User Login	Invalid login credentials	User receives an error message	Error message displayed	Success

Test Case: 2**Table 2. Add Product**

S.N.	Test case	Input	Expected result	Actual result	Status
1.	Adding of product	Entering product name, category and sub category	Adding of the product and details to the database.	The product details are added.	Success
2.	Deletion of Product	Entering product name, category and sub category	The product is deleted from database.	The product is deleted from database.	Success
3.	Product editing	Entering product name, category and sub category	The product is edited as per need.	The product is edited as per need.	Success

Test Case: 3**Table 3. Product Browsing and Selection**

S.no	Test case	Input	Expected result	Actual result	Status
1	Search for a Product	Enter a product name in the search bar	Relevant products are displayed	Products displayed as expected	Success
2	Add Product to Cart	Click "Add to Cart" for a product	Product is added to the shopping cart	Product added to the cart	Success
3	Remove Product from Cart	Click "Remove" for a product in the cart	Product is removed from the shopping cart	Product removed from the cart	Success
4	View Product Details	Click on a product for more information	Detailed product information is shown	Product details displayed	Success

Test Case: 4**Table 4. Checkout and Payment**

S.no	Test case	Input	Expected result	Actual result	Status
1	Proceed to Checkout	Click "Checkout" in the cart	User is taken to the checkout page	Checkout page displayed	Success
2	Enter Shipping Info	Provide shipping information	Shipping information is saved	Shipping info saved successfully	Success
3	Select Payment	Choose a payment method	Payment method is selected	Payment method selected	Success
4	Confirm Order	Click "Place Order"	Order is placed successfully	Order placed successfully	Success

Test Case: 5**Table 5. Order Details**

S.no	Test case	Input	Expected result	Actual result	Status
1	View Order List	Click on "Order"	User's order list is displayed	Order list displayed	Success

Test Case: 6**Table 6. Delivery Person Login**

S.no	Test case	Input	Expected result	Actual result	Status
1	Delivery Person Login	Entering valid login credentials	Delivery person is logged into the system	Delivery person logged in successfully	Success
2	Delivery Person Login	Entering invalid login credentials	Delivery person receives an error message	Error message displayed	Success
3	Delivery Person Login	Leaving username and password fields empty	Delivery person receives an error message	Error message displayed	Success

Test Case: 7**Table 7. Assign Delivery**

S.no	Test case	Input	Expected result	Actual result	Status
1	Admin Assigns Delivery	Select an order to assign	Order is assigned to the delivery person	Order assigned to delivery person	Success
2	Admin Assigns Delivery	Assign an order that is already assigned	Admin receives an error message	Error message displayed	Success

Test Case: 8**Table 8. Delivery Person Dashboard**

S.no	Test case	Input	Expected result	Actual result	Status
1	View Assigned Orders	Click on "Total delivery Orders"	List of assigned orders is displayed	Orders displayed as expected	Success
2	Logout	Click "Logout"	Delivery person is logged out	Delivery person logged out successfully	Success

Test Case: 9**Table 9. Status Updates**

S.no	Test case	Input	Expected result	Actual result	Status
1	System Updates Status	Order status changes automatically	Status is updated to reflect the current state	Status updated automatically	Success

Test Case: 10**Table 10. Customer Feedback Submission**

S.no	Test case	Input	Expected result	Actual result	Status
1	Customer Submits Feedback	Provide feedback	Feedback is submitted successfully	Feedback submitted successfully	Success
2	Customer Submits Empty Feedback	Leave all feedback fields empty	Customer receives an error message	Error message displayed	Success

Test Case: 11**Table 11. Admin Receives Feedback**

S.no	Test case	Input	Expected result	Actual result	Status
1	Admin Views Feedback	Click on "Feedback"	List of feedback messages is displayed	Feedback messages displayed	Success
2	Admin Responds to Feedback	Reply to a feedback message	Admin response is saved and associated with the feedback	Response saved successfully	Success

Chapter 5: Analysis and Evaluation

5.1 Analysis of Output obtained

The results we have seen from our online shopping system really show that we have hit the mark with what we wanted to achieve. Our main goal was to make shopping easy and safe for everyone who uses the system. At the same time, we wanted to offer a lot of different products so people have plenty of choices. The good news is that our system actually does make shopping easy and secure, just like we hoped. It's a place where users can comfortably buy things, knowing their safety is a priority.

When we look closer at what we have achieved, the way our system shows all the products in a clear catalog proves that we are giving users a chance to make smart decisions. Every product's information is easy to understand, helping shoppers choose what they really want. Also, the cart where users can put their chosen items works really smoothly. They can add things, change them, or remove them without any hassle. This matches our plan to create a shopping experience that's simple and flexible.

Another thing we aimed for was getting users involved. Our system lets customers share their thoughts through feedback, and that's a concrete way we have made sure to keep them engaged. By letting users express what they think, we're making sure we're on the same page and always improving. The fact that all of these outcomes fit right into what we wanted to achieve is a clear sign that our plan is working well.

Summing it all up, what we have achieved through these outcomes is a safe, easy, and enjoyable way to shop online. As these outcomes match perfectly with our main goals, we're in a great position to meet our customers' needs and wants. This success is showing us that our system is likely to keep attracting happy users, and it encourages us to keep making things even better as we go along.

5.2 Schedule analysis: Gantt chart

A Gantt chart is a visualization that helps in scheduling, managing, and monitoring specific tasks and resources in a project. The chart is the most widely used chart in project management. It is a useful way of showing what work is scheduled to be done on specific days.

Beginning Date: 16 February, 2023

Completed Date: 06 August, 2023

Weeks \ SDLC Phases	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17
Requirement Analysis																	
System Design																	
Coding																	
Testing and Debugging																	
Implementation																	
Documentation																	

Figure 8: Gantt chart

The diagram presented above provides a clear overview of the specific and relevant steps taken to progress through the various phases of the Online Shopping System project. The project commenced on February 16, 2023, and has since moved forward in a structured manner. As of now, sixteen weeks have elapsed, during which crucial stages have been successfully completed.

The initial stages encompassed essential tasks such as requirement analysis and system design. Subsequently, the project transitioned into the coding phase, where development efforts were accompanied by simultaneous testing and debugging processes. Throughout the entire duration, documentation was consistently underway, ensuring a comprehensive record of progress and decisions made.

This comprehensive approach has led to the successful implementation of the Online Shopping System. The project reached its finale on August 6, 2023, achieving its goals and objectives.

Chapter 6: Conclusion and Future Recommendations

6.1 Problem Faced and their implementation:

Introduction:

Online shopping systems offer convenience and accessibility to customers, but they also encounter challenges that can impact user experience, security, and overall system performance. Here are the problems faced and potential solutions for our online shopping project:

Slow Website Performance:

Problem: Users are frustrated by slow loading times, affecting engagement and conversions.

Solution: Compress images and minimize code to reduce page size.

Complex User Experience:

Problem: Users struggle with complicated navigation and checkout processes.

Solution: Design with user experience in mind, ensuring easy navigation and clear calls to action. Simplify the checkout process with minimal steps and clear guidance.

By implementing these solutions, the challenges faced by our online shopping system can be effectively addressed, resulting in an enhanced user experience, improved security, and increased customer satisfaction.

6.2 Conclusion:

Our “Online shopping system” enables users to browse, select, and purchase products or services conveniently over the internet. It encompasses a wide range of features and functionalities, including user registration, product catalog, shopping cart, secure payment processing, order management, search and filtering, feedbacks. The system aims to provide a seamless and enjoyable shopping experience for users while empowering businesses to efficiently manage their online sales operations. It is planned particularly that one can see all the updates of the versatile from any spot through on the web. It is very easy, time saving and comfortable; can order any product online than going to market for shopping. The availability of online shopping has produced a more educated consumer that can shop around with relative ease without having to spend a large amount of time. With the ever-increasing popularity of online shopping, an effective and robust online shopping system is crucial for businesses to thrive in the digital marketplace. Online shopping has opened up doors to many small retailers

that would never be in business if they had to incur the high cost of owning a brick and mortar store.

6.3 Future Recommendation:

Our designed online shopping system provides a 24×7 service that is customers can surf the website, place orders anytime they wish to. This system will reduce the manual operation required to maintain all the records of customer information. This technology can bridge the gap between the physical and digital shopping experiences, providing customers with a more realistic buying process. Other various improvement could be done for this online shopping system like real time delivery notification, better UI design, improve customer notifications with timely updates and product recommendations.

Real-Time Delivery Notification: Implementing real-time delivery notifications involves providing customers with instant updates on the status of their orders, from processing to shipping and delivery.

Better UI Design: Improving the user interface (UI) design focuses on creating a visually appealing and user-friendly interface that enhances the overall shopping experience.

Product Recommendations: Integrating product recommendations involves using algorithms to suggest products that are relevant to each customer based on their browsing history, past purchases, and preferences.
